ABSTRACT

Well-controlled fine MgTi$_2$O$_5$ powders, with pseudobrookite-type structure, are desired toward various industrial applications, however, commercial powders are hardly available to date. In this study, we focused the processing and characterization of well-controlled MgTi$_2$O$_5$ powders with/without LiF additive. MgCO$_3$ (basic) and TiO$_2$ anatase powders with/without 0.5 wt. % LiF additive were calcined in air at 1100 °C for 2 h to obtain the MgTi$_2$O$_5$ powders. SEM observation revealed that the non-doped MgTi$_2$O$_5$ powder consisted of equiaxed particles with the diameter of 0.5-1.5 μm, whereas, the LiF-doped MgTi$_2$O$_5$ powder consisted of elongated particles with the length of ~5-10 μm and the diameter of ~1.0-1.5 μm. The smooth surface of elongated MgTi$_2$O$_5$ particles demonstrates the effect of LiF doping as a flux, i.e., liquid phase formation during the reaction.

Keywords: MgTi$_2$O$_5$; pseudobrookite; porous ceramics; LiF, mineralizer; microstructure; elongated grains

1. INTRODUCTION

Double oxides with pseudobrookite-type structure (space group Cmcm (63), Figure 1) have characteristic unidirectional low-thermal expansion along with a-axis [1]. Among the pseudobrookite-type ceramics, aluminum titanate, Al$_2$TiO$_5$, is applied for next-generation diesel particulate filters (DPF) and so on due to its low bulk thermal expansion [2]. However, Al$_2$TiO$_5$ is thermodynamically metastable under 1200 °C and it gradually decomposes into Al$_2$O$_3$ and TiO$_2$ [3-5]. Furthermore, due to the strong anisotropy of thermal expansion, Al$_2$TiO$_5$ ceramics have poor mechanical properties caused by microcrack formation. Magnesium dititanate (MgTi$_2$O$_5$), with pseudobrookite-type structure, also has characteristic unidirectional low-thermal expansion, however, it is less crystallographically anisotropic and more thermally stable than Al$_2$TiO$_5$ [1]. Suzuki et al. have recently reported uniformly porous MgTi$_2$O$_5$ ceramics with 3-D network structure [6-9]. By controlling the stoichiometry and the liquid phase content, idiomorphic MgTi$_2$O$_5$ grains were formed [9].

Although well-controlled fine MgTi$_2$O$_5$ powders are desired toward various industrial applications, commercial powders are hardly available to date. From our previous study [9], LiF doping is effective to control the morphology of MgTi$_2$O$_5$ particles, however, the detail
has not yet been clarified. In this study, we focused the processing and characterization of well-controlled MgTi$_2$O$_5$ powders with/without LiF additive.

2. EXPERIMENTAL

Similarly to our previous work [6,7,9], commercially available MgCO$_3$ (basic) powder (99.9% purity, Kojundo Chemical Laboratory Co. Ltd., Saitama, Japan), TiO$_2$ anatase powder (99.9% purity, Kojundo Chemical Laboratory Co. Ltd.), and LiF powder (99.9%, Wako Pure Chemical Ind., Ltd, Osaka, Japan) were used as the starting materials. LiF acts as a mineralizer. Since the MgCO$_3$ (basic) powder contains plenty of OH groups and H$_2$O molecules, quantitative analysis of the starting powder was performed by thermogravimetry and differential thermal analysis (TG-DTA). Based on the compositional calibration using TG-DTA data, MgCO$_3$ (basic) and TiO$_2$ powders (nominally, Mg:Ti = 1:2 in mole fraction) with LiF (0.5 wt% for total starting powders) were wet-ball milled in ethanol for 24 h. The mixed slurry was vacuum dried, and the dried powder was put into the oven at 80 °C for 1 night. The mixed powder was then sieved through a 150-mesh screen. The mixed powders (i.e with and without 0.5 wt% LiF) were calcined in air at 1100 °C for 2 h (the ramp rate was 5 °C/min) to obtain the MgTi$_2$O$_5$ powders. The crystal structure of obtained powders was analyzed by X-ray diffraction method (XRD, Rigaku, Multiflex, Cu-K$_\alpha$, 40 kV and 40 mA). The microstructure of the powders was observed by field emission scanning electron microscopy (FE-SEM, SU-70, High High-Tech, Japan).
3. RESULTS AND DISCUSSION

Figure 2 shows XRD patterns of MgTi$_2$O$_5$ powders with and without LiF addition. The non-doped MgTi$_2$O$_5$ powder consisted of single-phase MgTi$_2$O$_5$, whereas the LiF-doped MgTi$_2$O$_5$ powder slightly containing MgTiO$_3$, which is an intermediate phase of the MgO-TiO$_2$ reaction system [6]. It is deduced that the intermediate MgTiO$_3$ phase might be also grown and somewhat stabilized with LiF doping.

**Figure 2.** X-ray diffraction patterns of non-doped LiF-doped and MgTi$_2$O$_5$ powder.

Figure 3 shows SEM micrographs of MgTi$_2$O$_5$ powders with and without LiF addition. The microstructure was remarkably different between two powders. The non-doped MgTi$_2$O$_5$ powder consisted of equiaxed particles with the diameter of 0.5-1.5 μm. On the other hand, the LiF-doped MgTi$_2$O$_5$ powder consisted of elongated particles with the length of ~5-10 μm and the diameter of ~1.0-1.5 μm. Some equiaxed particles found in the LiF-doped MgTi$_2$O$_5$ powder can be attributed to the MgTiO$_3$ particles, which was in good agreement with the XRD result. The smooth surface of elongated MgTi$_2$O$_5$ particles demonstrates the effect of LiF as a mineralizer, i.e., liquid phase formation during the reaction. The liquid phase enhanced anisotropic crystal growth of the pseudobrookite phase. These elongated particles are suitable for the applications of gas or liquid filter materials with low pressure loss.

4. CONCLUSIONS

In this study, we synthesized well-defined MgTi$_2$O$_5$ powders from MgCO$_3$ (basic) and TiO$_2$ anatase powders with/without LiF additive. The 0.5 wt% LiF-doped MgTi$_2$O$_5$ powder was composed of elongated MgTi$_2$O$_5$ particles with the length of ~ 5-10 μm and the diameter of ~1.0-1.5 μm. These elongated particles are suitable for the applications of gas or liquid filter materials with low pressure loss.

Acknowledgments

This work was supported by Grant-in-Aid for Science Research No. 23350111 for Basic Research: Category B. We thank Prof. Hiroya Abe at JWRI, Osaka University for his help on SEM observation. AtomWork database (NIMS) [10] and Vesta Ver. 3.1.8 software (Momma and Izumi [11]) were used for crystal drawing.
