Keywords: Effect of Poly Ethylene Glycol; CuO; Nanoparticles; Antibacterial Application

ABSTRACT. Pure CuO nanoparticles and chemically-precipitated Poly Ethylene Glycol (PEG) used as a capping agent CuO nanocrystal continuum (0.1, 0.2, 0.3, 0.4, 0.5 gm) was anatomized for structural and morphological research using X-ray diffraction (XRD), Fourier transform infrared spectroscopy (FT-IR) and Field - Emission Scanning Electron Microscopy (FE-SEM). Their X-ray Diffraction (XRD) analysis manifested monoclinic crystallinity in pure and PEG-capped CuO nanorods, with an average crystallite size of 21.63nm and 13-16nm respectively. The morphological analysis revealed their structural conformation. The FT-IR spectrum affirmed the presence of Cu-O bonds. The optical property of the aforesaid nanorods was studied by UV-Visible reflectance (UV-Vis DRS). The UV analysis showed that all the capped products show signs of good optical quality in the UV region and also the absorption edge was blue shifted with a band gap of 1.85 eV for 0.4gm PEG capped as results of quantum confinement effect. The antibacterial properties of the as-prepared nanostructures investigated for various human pathogens using disc diffusion method. The result showed the significant antibacterial activity both gram positive and gram negative bacteria.

1. INTRODUCTION

There has been a universal increase in common interests toward nanotechnology with progression in efficient nanomaterials which are extensively used in consumer and medical products. Because of the materials at nanoscale level behave in a different ideal way and posses ideal qualities from their other equivalents; it is the main reason for the significant succession in nanotechnology [1, 2]. Micro and nano structures have a well defined shape and inner structure because of their novel and fresh properties and diverging applications, when the size reduced to the nanometer regime, its properties changes considerably. However, the materials are customized at atomic level to reach its ideal properties such as high surface-to-volume ratio and quantum size effects and thus it can be tailored for the required applications [3]. The aggregations of nanoparticles are changes their size, shape and alter the chemical, physical and biological properties. It is therefore necessary to prevent the aggregation of the nanoparticles and to stabilize them at the desired size which can be achieved using chemical capping agents. Thus capping techniques, also called as stabilizers, plays an essential role in the synthesis of nanoparticles with reverence to size and shape control. The capping agents contain some functional groups which can ligate the metal nanoparticles [4]. However, there has been limited work on copper oxide nanorods and nanowires [5, 6]. Hence the present work was proposed at synthesizing the CuO nanoparticles with PEG as a capping agent and without capping agents. Among the a choice of metal oxides, CuO (p-type semiconductor with band gap of 1.2 eV) is of immense importance owing to its wide applications in heterogeneous catalysis, gas sensing, lithium electrode material, solar cells, reactive oxidizers in nanothermite composites, and so forth. CuO has also been predictable as attractive oxygen carrier for capturing and parting of CO2 with little energy loss in chemical looping combustion of fossil fuels and waste to diminish the greenhouse gas emissions. [7]

Thi My Durg Dang et al., stated that PEG works as size controller and also as a surfactant of nanoparticles [8]. PEG is commonly used as a surfactant to prepare nanomaterials and as a preservative of metal colloids because of its availability, low expenditure and non toxicity. Apart
from usage of PEG as a surfactant, PEG is used as one of the finest non-ionic polymers in biomedical science [9]. CuO nanorods were obtained through the reaction of cupric dodecyl sulfate (Cu (DS)₂) and NaOH at 80 °C using a solution phase synthesis was case out by Qi Liu et al [10]. Ultrasound assisted shape regulation of CuO nanorods in ionic liquids and their use as energy efficient lubricant additives were investigated by Rashi Gusain et al., [11].

The potential work done with some resistant bacteria strains, the antibacterial activity involving both pristine and PEG capped CuO nanorods for their unique properties has upheld to be of great worth and has yielded more major attractions as a possible one for the concern caused by hospital contagion harmful microorganisms are essentially caused by both Gram positive and Gram negative microorganisms such as B.subtilis, S.aureus, P.vulgaris, E.coli and V.cholerae. There-fore there is an increasing demand for novel antibacterial agents, and recently, due to their high antibacterial activity metal nanoparticles have attracted the attention of medical microbiologists world-wide. Although, unlike silver and copper antibacterial activity of copper oxide is not being studied extensively.

Among many processes, for large range production, simple chemical precipitation method has been considered to be the most on the go method as it is behind to low cost, high capacity and fine potential for high quantity production [12]. To analyze the manipulation of PEG as a capping agent in pure CuO nanoparticles, a thumping attempt has been made by varying the concentration of the capping agent on the structural and morphological parameters on synthesized CuO nanoparticles and to study its antibacterial activity.

2. EXPERIMENTAL METHODS

2.1. Chemicals

Copper acetate monohydrate (Cu (CH₃COO)₂.H₂O), sodium hydroxide (NaOH) pellets and polyethylene glycol [HO(C₂H₄O)nH] (PEG, MW: 8000) were purchased from Merck, India and used as received exclusive of any further purification. Since they were of analytical reagent grade with 99% purity. De-ionized water was used all the way through the synthesis and ethanol was used for the washing purpose.

Bacterial used:

The antibacterial activity of prepared nanoparticles were investigated against five strains of Gram positive Bacterial strain namely Staphylococcus aureus (NCIM 2901), Bacillus subtilis (NCIM 2063) and gram negative bacterial strains such as Proteus vulgaris (NCIM 2027), Escherichia coli (NCIM 2256) and Vibrio cholerae (ATTC 14033) was obtained from National Collecting Industrial Microorganism (NCIM), Biochemical Sciences Division, National Chemical laboratory, Pune.

The stock cultures were maintained on nutrient agar medium at 7 °C for 24 h, antibacterial activity was determined by using Muller Hinton Agar (MHA) and Muller Hinton Broth (MHB) obtained from Himedia Ltd, Mumbai.

2.2. Synthesis of CuO nanostructures

For the synthesis of pristine CuO nanocrystals, 1.99 g (0.2 M) of copper acetate in 50 ml of deionised water was allowed to stirrer and then 1.2 g (0.6 M) of sodium hydroxide (NaOH) pellets were mixed drop by drop to the above prepared solution. The intact mixture was stirred magnetically at 60°C until a homogeneous solution was obtained and also it was stirred constantly until a black precipitate was produced. The obtained dispersions were purified by washing next to de-ionized water and ethanol alternately a number of times to eliminate impurities and followed by revelation in oven to get a dried nanoparticles. In order to obtain the pure crystalline rods the dried particles were annealed for 2 hours at 400°C.

2.3. Synthesis of PEG capped CuO nanocrystals

In the synthesis process, 0.2M of copper acetate in 50ml deionised water was stirring in magnetic stirrer. Then diverse weights (0.1, 0.2, 0.3, 0.4 and 0.5gm) of PEG were added to the above solution. The mixture was stirred magnetically at 60°C until a homogeneous solution was
obtained. After that 0.6 M of NaOH pellets was added drop by drop to the above mixture and stirred magnetically until a black precipitate was formed. The precipitate was washed, dried and then annealed as discussed in the above progression. Fig. 1 shows the flowchart of the preparation process of CuO nanoparticles.

2.4 Characterization

The crystal structure and phase purity of the as synthesized products were investigated by X-ray diffractometer (X’ PERT PRO) with Cu Ka radiation (λ=1.5406Å). FTIR have been employed to find the presence of functional groups in the range of 4000-400cm⁻¹ and it was recorded using SHIMADZU-8400 with a resolution of 4cm⁻¹. Measurements were performed with pressed pellets which were made using KBr powder as diluents. UV visible spectrum was monitored with JASCO UV V-670 Spectrophotometer to know the optical property of the synthesized samples. The morphology of the products was examined using Philips Field Emission Scanning Electron microscopy (FESEM). The antibacterial activity was done using disc diffusion method.

2.5 Antibacterial assays

Disc diffusion method

The antibacterial activity of compounds was determined by disc diffusion method according to Bauer et al. (1966) [13] with modification. Petri plates were prepared by pouring 20 mL of MHA for bacteria and then the plates were allowed to solidify and used in susceptibility test. The standard inoculum using bacterial suspensions containing 10⁸ CFU per mL was swabbed on the top of the solidified respective media and allowed to dry for 10 minutes. The prepared nanoparticles were dissolved in 10 per cent Dimethyl sulfoxide (DMSO) and under aseptic conditions, sterile discs were impregnated with compounds of 200 µg/disc. The discs with compounds were placed on the surface of the medium with sterile forceps and gently pressed to ensure contact with inoculated agar surface. Ciprofloxin (5µg/disc) for bacteria was used as positive control and 10 per cent DMSO was used as blind control. Finally, the inoculated plates were incubated at 37°C for 24 h for all the bacterial strains. The zones of inhibitions were observed and measured in millimeters. The assay in this experiment was repeated three times.

2.6. Micro dilution broth assay

Determination of the minimum inhibitory concentration (MIC) for bacteria

The MIC of prepared nanoparticles were determined in MHB by using a microtitre plate assay as reported by Hammond and Lambert (1978) [14] 100 µL of Sterile MHB for bacteria were transferred in to each well of sterile 96 micro titer well plate. The both samples were dissolved in 10%
percent DMSO to obtain 400 µg/mL (compounds) stock solutions respectively. A volume of 100 µL of prepared nanoparticles stock solution was added into the first well. After fine mixing of the compounds and broth 50 µL of solution was transferred to the second well and in this way, the serial dilution procedure was continued to a twofold dilution to obtain concentrations like 200 to 7.81 µg/mL (compounds) of each well. Finally, 5 µL of bacterial suspension was added to each well to achieve concentrations of approximately 5 ×10^5 CFU/mL. Each plate was a setup positive control (bacterial suspension adding 10 µL of MHB) and negative control (10 % DMSO and bacterial culture). The plates were incubated at 37 °C for 24 h for all the bacterial strains. The lowest concentration occurred was taken as the MIC value.

3. RESULT AND DISCUSSION

3.1 Structural analysis

The XRD patterns of uncapped and altered weights of PEG capped (0.1, 0.2, 0.3, 0.4 and 0.5gm) CuO nanocrystals are shown in Fig. 2. The obtained diffraction planes value is in good co-ordination with the JCPDS card No: 89-5899. It is also confirmed the monoclinic structure of CuO nanoparticles.

![Fig. 2 XRD spectrum of Pure and Various concentration of PEG capped CuO nanocrystals](image-url)

XRD pattern show no peaks of impurity with the cleared spectrum. From the XRD pattern the crystalline size were estimated for as-prepared samples. From the X-ray diffraction peak widths, the diameter of the nanocrystals was estimated through Scherrer formula [15]. The average size of the particles estimated is 21.63 nm for uncapped. However, the estimated sizes of the capped particles are 16.32, 15.85, 13.97, 13.06 and 14.21 nm for capping concentrations of 0.1, 0.2, 0.3, 0.4 and 0.5gm respectively. When compared with uncapped artefact, all the capped particles show reduced size as a result of capping. The mechanism behind the formation of size reduced particle is explained as follows. After introducing polymer into their action mixture, Cu²⁺ ions form a complex with PEG, ensuing in particle capping in the lead nucleation [16].

3.2 Functional Analysis

To understand the role of PEG on the synthesis of CuO nanoparticles, FT-IR spectra were recorded in the range between 4000 and 400 cm⁻¹. Fig. 3 illustrates the FT-IR spectra of uncapped and diverse weights of PEG capped CuO nanocrystals. All the samples exhibit a broad absorption band in the range of 3330–3500 cm⁻¹ due to stretching vibration of OH.
The band at 2360 cm$^{-1}$ assigned to carboxylic group (COO$^-$) vibration in which the intensity was little high for uncapped and it gets decreases on adding the weights of PEG from 0.1gm onwards, and reached optimum at 0.4gm of capping of CuO nanoparticles. The presence of a peak at 1456 cm$^{-1}$ and around 1650 cm$^{-1}$ corresponding to C=C stretching and C=N stretching respectively. As shown in fig. 3, PEG capped samples show absorption bands at 2920 cm$^{-1}$ due to CH asymmetric stretching vibrations. The absorption band positioned at around 2860 cm$^{-1}$ is resulted from characteristic peak of PEG. The band centred at 1247 cm$^{-1}$ originates from C O C bands of PEG [17]. The absorption bands indicate around 420, 530, and 590 cm$^{-1}$ are due to the Cu-O stretching in the monoclinic structure of CuO [18].

3.3 Optical property
3.3.1 UV-Vis spectroscopy
The UV-Visible spectroscopy of the pristine and PEG capped CuO nanocrystals were shown in the figure 4. From the figure, it is well-known that the peak position has no change with reverence to the capping concentrations.

However, on 0.4gm of PEG capping, the absorption edge was blue shifted with a band gap of 1.85 eV as a result of quantum confinement effect. Quantum confinement effect occurs in the case of the nanoparticles when the particle size becomes as good as with or slighter than the exciton Bohr radius. All the capped products show signs of good optical quality in the UV region. As the concentration of PEG inclusion increases, the absorption edges are blue shifted with an intensity reduction in the reflectance due to quantum confinement effect. The band gap of pure CuO is found to be 1.76 eV; whereas the values of PEG capped CuO with 0.1, 0.2, 0.3, 0.4, and 0.5 gm of PEG ions are about 1.80, 1.82, 1.84, 1.85, and 1.72 eV, respectively. Up to 0.4gm addition of PEG the band gap gets increases, after that the effect of capping will get increase and thus the band gap gets decreases. From this it can be observed that 0.4gm of PEG capped nanorods may be considered as the optimum capping level of CuO nanocrystals.
3.4 Morphological Analysis

3.4.1 FESEM

Figure 5(a, b) shows the FESEM images of pure and 0.4 gm PEG capped nanoparticles. The FESEM image of uncapped CuO sample illustrates the formation of CuO nanorods with less degree of aggregation and its length of typically about 100-250nm. The vary in morphology of the CuO nanoparticles as a role of PEG capping is evidenced by FESEM image presented in fig 6(b). The flower-like nanostructures consisted of nanorods has been observed and also the rods are joined together to form Plate like formation with its length typically about 50 to 250nm was observed in PEG capped CuO nanoparticles.

Fig. 5 FE-SEM images for uncapped and 0.4gm PEG capped nanorods

Here PEG plays a considerable role in preventing the flocculation of particles, controlling the particle size and its morphology. FESEM data established that PEG addition has a substantial effect on the morphology and size distribution of the obtained material.

3.5 Antibacterial Activity

Antibacterial testing for antibacterial activity revealed that both the prepared nanoparticles acted as an excellent anti bacterial agents for both gram positive and gram negative bacteria which is shown in the fig. 6.

Fig. 6 Antibacterial activity photograph of different bacteria for pristine CuO and 0.4gm PEG capped CuO nanoparticles.

The activity was studied against gram +ve bacteria strains namely *Bacillus subtilis* and *Staphylococcus aureus* and gram –ve bacteria strains namely *Proteus vulgaris, Escherichia coli* and *Vibrio cholerae*. The bacterial inhibition zones for CuO nanorods for both pure and PEG capped CuO nanoparticles are shown in the Table. 2 and it was compared with standard Ciprofloxin. From the table it was proved that the prepared nanoparticles exhibit a remarkable activity against human pathogens which is near to the value of standard. The highest mean zone of inhibition of 31 mm was developed against B. subtilis and E.coli for PEG capped (0.4 gm) CuO nanorods. For all the bacterial strains comparing pristine, PEG capped nanoparticles shows the better zone of inhibition. Several studies have suggested two possible mechanisms for the interaction between the bacteria and the nanoparticles. The primary reason is the production of increased levels of reactive oxygen...
species (ROS). The oxygen species are mostly in the form of hydroxyl radicals and singlet oxygen. The next reason is the deposition of the nanoparticles on the surface of bacteria [19]. In addition, the MIC values of nanoparticles against all the five pathogens are listed in Table 1. The results of the lowest MIC values of the CuO nanostructures ranged between 6.25 and 25 µg/ml.

Gram-positive bacteria have thicker peptidoglycan cell membranes compared to the Gram-negative bacteria, and it is harder for CuO to penetrate it, still our synthesized nanoparticles of both pure and capped nanoparticles shows the proper response for all the human pathogens. The extent of inhibition of bacterial growth reported in this study clearly shows the effect of capping on CuO nanoparticles.

### 4. CONCLUSION

In conclusion, the results evince that a simple noncomplex chemical precipitation method endued a facile and efficient route to synthesize PEG-capped CuO nanocrystal continuum of desired grades. However, the size of the particles were evidently influenced by the percentage of capping, principally proclaiming reduction in size of the nanoparticles as a result of capping (13.06 nm) when juxtaposed to their pristine counterpart. FESEM studies of PEG (0.4gm) capped particles show a considerable effect on the morphology and size distribution of the obtained artefacts. Comparing pristine CuO, the antibacterial activity of PEG capped CuO nanorods developed a highest zone of inhibition for all the human pathogens. Obtained values of MIC for all the strains suggest that the prepared copper oxide nanoparticles shows excellent antibacterial activity and can be used as promising antibacterial agents in wide applications. Upon contemplating the above factors, 0.4gm of PEG as the capping agent is elicited as the optimum level for the preparation of CuO nanoparticles in order to control the size of the particle and for the morphology and also for the potent antibacterial applications.
