ABSTRACT

The mitotic and meiotic behaviour is considered to be one of the most dependable indices to estimate the potency of mutagen cytological aberrations in plants serve as an excellent monitoring system for the determination of mutagens that may cause a genetic hazard in the present study cluster bean contains 7 bivalents ($2n = 14$) for the present investigation the plant exposed to different concentration of 60, 80, and 100kr gamma rays and 0.4, 0.6 and 0.8 % Mm (EMS) the present study reveals various chromosomal aberration includes stickiness precocious movement, single and anaphase bridge lag and synchronized movement of chromosomes at anaphase.

Keywords: chemical mutagens; *Cyamopsis tetragonoloba*; bean

1. INTRODUCTION

Legumes are considered as the major source of dietary protein and amino acid for man and farm animals (Baudoin and Maquet, 1991). A major part of the human diet all over the world consists of cereals and legumes (Mandal and Mandal, 2000). According to estimation of FAO, 70 % of human food comprises cereals and legumes and the remaining 30 % comes from animals (FAO, 1970). Pulses also play an important role as sustainable agricultural by maintaining and restoring soil fertility through biological nitrogen fixation (Asthana, 1998). In India, pulses are generally grown on marginal or sub-marginal lands which have very poor fertility status (Punjari and Sheelvantar, 2001). It is a cheap source of dietary protein (24 %), which also contains 60 % carbohydrate, 2 % fat and rich amount of vitamins and phosphorous (Venkatesan, 1997).

Cluster bean (*Cyamopsis tetragonoloba* (L.) Taub) belongs to the family Fabaceae. It's an annual summer legume crop of India and Pakistan. It is grown in over area of about 242.6 thousand tons annually with an average yield 909.7 kg/ha (Anonymous, 2003). It is also an important short duration multi-purpose legume and cultivated throughout the tropics and sub-tropics areas. The green pods are used as vegetable and fodder.

2. MATERIAL AND METHODS

In the present investigation, one of the genotype of cluster bean variety namely “Pusa Navabahr” was collected from Millet Breeding Station, Tamil Nadu Agricultural University, Coimbatore, Tamil Nadu. The present research work was carried out in Cytology laboratory and Botanical Garden of the Department of Botany, Annamalai University, Annamalai Nagar, Tamil Nadu.

This study was through induced mutation by physical and chemical mutagens namely, gamma rays, Ethyl Methane Sulphonate (EMS), Sodium Azide (SA) and Colchicine (COH) and their effects on quantitative and qualitative traits like early maturing, high yielding and improved protein content of cluster bean variety Pusa Navabahr by means of extending the genetic variability with cytological constituents.

For mitotic studies young and healthy root tips were collected between 8.45 to 9.30 am and thoroughly washed in water. They were pre treated in 0.002 M hydroxyl quinoline at 4 °C for 3 hrs. Then, the root tips were thoroughly washed in water and fixed in 1:3 acetic alcohol for 3 hrs overnight. Again the root tips were washed in distilled water. Then the root tip squashes were prepared following iron alum haematoxylin squashes technique (Marimuthu and Subramaniam, 1960). Squash were made with one or two root tips per slide and temporarily sealed. The iron alum haematoxylin staining method was found to be more satisfactory in counting number and studying the morphological features of the chromosomes.

3. RESULTS AND DISCUSSION

In control plants, Gamma radiation treated plants, EMS and sodium azide treated plants, only diploid cells with $2n = 14$ chromosomes have been observed. This suggests that may be point mutations or gene mutations taken place.

In control, the root tip cells show $2n = 14$ chromosomes and no mitotic aberrations have been observed. But, in gamma radiation treated plants along with $2n = 14$ chromosomes irregular pairing up of chromosomes and precious movement of them have been noted. In EMS treated plants along with cells having $2n = 14$ chromosomes cells with irregular arrangements of chromosomes, broken metaphases and anaphase bridges have been also observed. In sodium azide treated plants along with cells having $2n = 14$ chromosomes, rare occurrences of anaphasic bridges and laggards have been noted. In colchicine treated plants occurrence of $4n = 28$ chromosomes (polyploids) in more number of cells have been observed. Besides, mitotic aberrations like broken metaphase, irregular anaphase, anaphasic laggards and anaphasic bridges occur more frequently. Such aberrations are not observed in control plants (Plates I and II).

In colchicine treated plants, along with diploid cells, polyploid cells also have been observed, mostly tetraploid cells and rarely triploid ($3n$), haploid (n) and pentaploid cells ($5n$) in the root tips.

The details about the percentage occurrence of mitotic aberrations in the root tip cells particularly broken metaphases, anaphasic laggards and anaphasic bridges in various control gamma radiation treated plants (60, 80 and 100 kR), EMS treated plants (0.4, 0.6 and 0.8 %), sodium azide treated plants (0.02, 0.03 and 0.04 %) and colchicine treated plants (0.12, 0.14 and 0.16 %) are furnished in (Table 1.).

PLATE II

MITOTIC ABERRATIONS

Table 1

Mutagens	Treatments dose/conc.	Number of cells observed	Broken metaphase	Percentage of occurrence	Number of cells observed	Anaphasic laggard	Percentage of occurrence	Number of cells observed	Anaphasic bridge	Percentage of occurrence
Gamma Rays	Control	86	-	-	93	-	-	102	-	-
	60 kR	98	4	4.08	84	3	3.571	98	1	1.020
	80 kR	120	7	5.833	102	6	5.882	115	4	3.478
	100 kR	144	11	7.638	116	8	6.896	120	7	5.833
EMS	Control	81	-	-	76	-	-	96	-	-
	0.4%	89	2	2.247	89	2	2.247	112	3	2.678
	0.6%	112	4	3.571	108	4	3.703	109	5	4.587
	0.8%	142	7	4.929	128	7	5.468	130	8	6.153
SA	Control	92	-	-	84	-	-	112	-	-
	0.02%	110	3	2.727	101	4	3.960	116	4	3.448
	0.03%	137	5	3.649	124	6	4.838	120	7	5.833
	0.04%	125	8	6.400	120	7	5.833	132	9	6.818
COH	Control	99	-	-	101	-	-	110	-	-
	0.12%	148	11	7.432	126	5	3.968	115	6	5.217
	0.14%	156	13	8.333	148	9	6.081	125	11	8.800
	0.16%	128	16	12.500	124	10	8.064	136	15	11.029

4. CONCLUSIONS

It is clear from the table that the more dosage level, the higher is the percentage of mitotic aberrations in gamma radiation, EMS, sodium azide and colchicine treated plants. Along with broken metaphases, anaphasic laggards and bridges, other types of abnormalities like clumping up of chromosomes, unequal anaphase, precocious movements of chromosomes during metaphases have been also rarely observed in all the plants treated with mutagenic agents and colchicine. It is clearly understood that the mitotic aberrations are more in colchicine treated plants than the plants treated with gamma rays, EMS and sodium azide.
