ABSTRACT

The present study was aimed to assess the antihyperlipidemic, antihypertensive and antioxidant effect of D-carvone, a monoterpene against N^o-nitro-L-arginine methyl ester hydrochloride (L-NAME) induced hypertension. Hypertension was prompted in adult male albino rats of the Wistar strain by oral administration of the L-NAME (40 mg/kg body weight) in drinking water for 4 weeks. Rats were treated with D-carvone (5, 10 and 20 mg/kg body weight) for four weeks. L-NAME treated rats exhibited significant increase in water intake, heart rate, aortic lipids level such as triglycerides (TG), total cholesterol (TC), free fatty acids (FFA) and significant decrease in the level of phospholipids (PL), plasma nitric oxide (NO). The activities of superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPx) were decreased in erythrocytes of L-NAME induced hypertensive rats. Treatment with D-carvone restored all the above parameters to near normal level. These results suggest that D-carvone acts as an antihyperlipidemic, antihypertensive and antioxidant agent against L-NAME induced hypertensive rats.

Keywords: L-NAME; Lipids; Nitric oxide; Antioxidant; D-carvone

1. INTRODUCTION

Hypertension is one of the most important risk factors for CVD (Gu et al., 2002). It afflicts more than 1 billion adults world-wide and 90-95% of these patients have essential hypertension (Whitworth, 2003). Dyslipidemia is a broad term which implies imbalance between elevated circulating levels of cholesterol and it occurs concomitantly in over one-third of patients with hypertension (Wong et al., 2006). The primary function of nitric oxide is the regulation of vascular tone, inhibition of VSMC proliferation and platelet aggregation (Dias-Junior et al., 2008) which makes chronic inhibition of basal nitric oxide with an orally active nitric oxide synthase inhibitor (L-NAME), a particularly interesting model of hypertension. Bioavailability of NO can be maintained by inhibition of oxidative stress, and therefore the agents with antioxidant properties inactivating free radicals increase NO bioavailability and can improve regulation of vascular tone (Kumar et al., 2010).

Recent evidence indicates that oxidative stress as the main mechanism is responsible for cardiovascular complications such as alteration in lipid metabolism (Palmieri et al., 2006). Oxidative stress, originally described as an altered balance between the production of free radicals and antioxidant defenses, is an important phenomenon in different physiological and pathological processes (Chang and Wu, 2006). In hypertensive animals, reactive oxygen species (ROS) are increased and superoxide dismutase, which converts O_2 to H_2O_2 , is reduced, suggesting that an imbalance between oxidant and antioxidant mechanisms is a contributing factor (Beswick et al., 2001; Thakali et al., 2006).

Many researchers are actively looking for antihypertensive compounds derived from various natural products for the use in functional foods (Diebolt et al., 2001; Grassi et al., 2005). In recent years, the prevention of cardiovascular diseases has been associated with ingestion of fresh fruits, vegetables or plants rich in natural antioxidants. The use of natural products as an alternative to the conventional treatment of cardiovascular diseases has been on the rise in the past few decades. Monoterpenes are primary compounds of plant essential oils and the effects of many medicinal herbs have been attributed to them. D-carvone is a monoterpene, present in the essential oils of many medicinal and aromatic plants (Caraway, dill and spearmint) that are endowed with many biological activities including antioxidant, antimicrobial, fungicidal, insecticidal (Johri, 2011) and anticancer properties (Vinothkumar et al., 2013). D-carvone has long been used as a natural medicine for the treatment of many acute, as well as chronic conditions. These include diabetes and cancer (Muruganathan et al., 2013; Vinoth kumar et al., 2013). Therefore, in the present study we investigated the effects of D-carvone on heart rate, lipid level, nitric oxide and enzymatic antioxidants in nitric oxide deficient hypertensive rats.

2. MATERIALS AND METHODS

2.1. Source of chemicals and experimental animals

D-carvone and L-NAME were purchased from Sigma-Aldrich (St. Louis, Missouri, USA). All other chemicals used in this study were of analytical grade obtained from Merck and Himedia, India.

Male albino (9 weeks-old) rats of Wistar strain with a body weight ranging from 180 to 220g were procured from the Central Animal House, Department of Experimental Medicine, Rajah Muthiah Medical College and Hospital, Annamalai University, and were maintained in an airconditioned room ($25 \pm 1^\circ C$) with a 12 h light/12 h dark cycle. Food and water were provided ad libitum to all the animals. The study was approved by the Institutional Animal Ethics Committee of Rajah Muthiah Medical College and Hospital (Reg No.160/1999/CPCSEA, proposal number: 1082), Annamalai University, Annamalainagar.

2.2. Induction of hypertension and administration of D-carvone

Animals were given L-NAME in drinking water at a concentration of 0.4 mg/ml to account for a daily intake of 40 mg/kg throughout the experimental period (30 days) (Saravana kumar et al., 2011). D-carvone was suspended in 1% DMSO just before treatment and administered everyday orally to rats using an intragastric tube at any one of the following doses of 5, 10 and 20 mg/kg body weight daily for a period of four consecutive weeks.

2.3. Experimental timeline

The rats were randomly divided into six groups each consisting of six rats.

Group I —control rats (animals that received only normal diet and water);

Group II —control + D-carvone (20 mg/kg/body weight);

Group III —L-NAME control rats;

Group IV —L-NAME + D-carvone (5 mg/kg/bodyweight)

Group V —L-NAME + D-carvone (10 mg/kg/bodyweight)

Group VI —L-NAME + D-carvone (20 mg/kg/bodyweight).

The experimental duration was 30 days. On 31st day, the rats were sacrificed by cervical dislocation. Blood was collected (orbital sinus with great care) in a dry test tube and allowed to coagulate at ambient temperature for 40 min. The serum was separated by centrifugation at $224\times g$ for 10min. The blood collected in a heparinized centrifuge tube and centrifuged at $224\times g$ for 10min and the plasma was separated by aspiration. After the separation of plasma, the buffy coat, enriched in white cells, was removed and the remaining erythrocytes were washed three times with physiological saline. A known volume of erythrocyte was lysed with hypotonic phosphate buffer at pH 7.4. The hemolysate was separated by centrifugation at $350\times g$ for 10min and the supernatant was used for the estimation of enzymatic antioxidants.

Aortic tissues were (250 mg) sliced into pieces and homogenized in appropriate buffer in cold condition (pH 7.0) to give 20% homogenate (w/v). The homogenate was centrifuged at $560 \times g$ for 10 min at 4°C in refrigerated centrifuge. The supernatant was separated and used for various biochemical estimations.

2.4. Measurement of blood pressure by non-invasive method

Before commencement of the experiment, animals were trained with instrument for measuring blood pressure. In all groups of animals, heart rate was recorded every week during the entire period of the study noninvasively using a tail-cuff method according to standard procedures (IITC, model 31, USA). Values reported are the average of three sequential measurements. All the recordings and data analyses were done using a computerized data acquisition system and software.

2.5. Nitric oxide metabolites level

Nitrite and nitrate [stable nitric oxide metabolites] in the plasma samples were measured based on the Griess reaction (Green et al., 1982).

2.6. Estimation of total cholesterol and triglycerides

Tissue lipids were extracted by the method of Folch et al. (1957) using chloroform: methanol mixture (2:1 v/v). The levels of total cholesterol (TC) were estimated by the method of Zlatkis et al. (1953). Lipid extract of 0.5 ml was evaporated to dryness. To this, 5.0 ml of ferric chloride - acetic acid reagent was added. The tubes were mixed well and 3.0 ml of concentrated sulphuric acid (H_2SO_4) was added. A series of standards containing cholesterol in the range 3–15 μg were made up to 5.0 ml with the reagent and a blank containing 5.0 ml of the reagent was prepared. The absorbance was read after 20 minutes at 560 nm.

The content of triglycerides (TG) was estimated by the method of Fossati and Prencipe (1982). Lipid extract of 0.5 ml was evaporated to dryness. To this, 0.1 ml of methanol was added followed by 4.0 ml of isopropanol. About 0.4 g of alumina was added to all the tubes and shaken well for 15 minutes. It was centrifuged and then accurately 2.0 ml of the supernatant was transferred to appropriately labeled tubes. The tubes were placed in a water bath at 65°C for 60 minutes for saponification after adding 0.6 ml of the saponification reagent followed by 0.1 ml of sodium metaperiodate and 0.5 ml of acetyl acetone reagent. After mixing, the tubes were kept in a water bath at 65°C for an hour. A series of standards of concentration 8-40 µg triolein were treated similarly along with a blank containing only the reagents. All the tubes were cooled and read at 405 nm.

2.7. Estimation of free fatty acids and phospholipids

Free fatty acid (FFA) level was estimated by the method of Falholt et al. (1973). An aliquot (0.5 ml) of the lipid extract was evaporated to dryness. To this, 1.0 ml of phosphate buffer, 6.0 ml of extraction solvent, and 2.5 ml of copper (Cu-TEA) reagent were added. All the tubes were shaken vigorously for 90 seconds and were kept aside for 15 minutes. Then the tubes were centrifuged and 3.0 ml of the upper layer was transferred to another tube containing 0.5 ml of diphenylcarbazide solution and mixed carefully. The absorbance was read at 550 nm after 15 minutes. A reagent blank containing (1.0 ml) of phosphate buffer was processed as blank.

Phospholipid (PL) level was estimated by the method of Zilversmit and Davis (1950). An aliquot of 0.5 ml of the lipid extract was pipetted out into a Kjeldahl flask and evaporated to dryness. To the extract, 1 ml of 5 N H₂SO₄ was added and digested in a digestion rack till the appearance of light brown color. Two to three drops of concentrated nitric acid was added and the digestion continued till it became colorless. The Kjeldahl flask was cooled and 1.0 ml of distilled water was added and heated in a boiling water bath for about 5 minutes. Then, 1.0 ml of 2.5% ammonium molybdate and 0.1 ml of 1-amino-2-naphthol-4-sulfonic acid were added. The volume was then made upto 5.0 ml with distilled water and the absorbance was measured at 660 nm within 10 minutes.

2.8. Determination of enzymatic antioxidants

Superoxide dismutase (SOD) activity was assayed in the erythrocyte and tissues by the method of Kakkar et al. (1984). Erythrocytes (0.5 ml) were diluted to 1.0 ml with distilled water followed by addition of 2.5 ml of ethanol and 1.5 ml of chloroform (all reagents chilled) was added. This mixture was shaken and then centrifuged. The enzyme activity in the supernatant was determined. The assay mixture contained 1.2 ml of sodium pyrophosphate buffer, 0.1 ml of phenazine methosulphate, and 0.3 ml of nitroblue tetrazolium and appropriately diluted enzyme preparation in a total volume of 3ml. The reaction was started by the addition of 0.2 ml of nicotinamide adenine dinucleotide (NADH). After incubation at 30°C for 90 s, the reaction was arrested by the addition of 1.0ml of glacial acetic acid. The reaction mixture was stirred vigorously and shaken with 4ml of n-butanol. The mixture was allowed to stand for 10 min; centrifuged and n-butanol layer was separated. The color density of the chromogen in n-butanol was measured at 510 nm against butanol blank.

The activity of catalase (CAT) in the erythrocyte was assayed by the method of Sinha (1972). To 0.9ml of phosphate buffer, 0.1ml of erythrocyte and 0.4ml of H₂O₂ were added. The reaction was arrested after 60 s by adding 2ml of dichromate-acetic acid mixture. The tubes were kept in a boiling water bath for 10 min and the color developed was read at 620 nm.

The activity of glutathione peroxidase (GPx) in the erythrocyte was measured by the method of Rotruck et al. (1973). To 0.2 ml of Tris buffer, 0.2ml of ethylene diamine tetra acetic acid (EDTA), 0.1ml of sodium azide, and 0.5ml of erythrocyte were added. To the mixture, 0.2 ml of glutathione followed by 0.1ml of H₂O₂ was added. The contents were mixed well and incubated at 37°C for 10 min along with a tube containing all reagents except the sample. After 10 min, the reaction was arrested by the addition of 0.5ml of 10% TCA. The tubes were centrifuged and the supernatant was used for the estimation of glutathione.

2.9. Statistical analysis

Statistical analysis was performed by one-way analysis of variance followed by Duncan's multiple range test using statistical package for the social science (SPSS) software version 11.5. Results were expressed as mean $\pm$ S.D. for six rats in each group. A value of $P < 0.05$ was considered to be statistically significant.

3. RESULTS

3.1. Effect of D-carvone on heart rate and water intake

Figs. 1 and 2 shows the effect of D-carvone on heart rate and water intake in control and L-NAME induced hypertensive rats. Heart rate and water intake were increased significantly ($P < 0.05$) in L-NAME induced hypertensive rats when compared with control. Treatment with D-carvone (5, 10, & 20mg/kg) significantly ($P < 0.05$) reduced the heart rate and water intake in L-NAME induced hypertensive rats. The 20 mg/kg dose showed better effect in reducing heart rate and water intake than other two doses (5 and 10 mg/kg), and also in our previous study the 20 mg/kg dosage showed higher effect, so we have chosen 20 mg/kg dosage for further evaluation.

Fig. 1. Effect of D-carvone on heart rate in control and L-NAME induced hypertensive rats.

Columns are mean $\pm$ S.D. for six rats in each group. Data were analyzed by one-way ANOVA followed by Duncan's multiple range test (DMRT). *P<0.05 compared with the control. #P<0.05 compared with the L-NAME. \$P<0.05 compared with the D-carvone (10 mg/kg) group.

Fig. 2. Effect of D-carvone on water intake in control and L-NAME induced hypertensive rats.

Columns are mean $\pm$ S.D. for six rats in each group. Data were analyzed by one-way ANOVA followed by Duncan's multiple range test (DMRT). *P<0.05 compared with the control. #P<0.05 compared with the L-NAME. \$P<0.05 compared with the D-carvone (10 mg/kg) group.

3.2. Effect of D-carvone on aortic lipids

Table 1 depict the levels of lipids (TC, TGs, FFAs, and PLs) in aorta of control and L-NAME hypertensive rats. The levels of lipids (TC, TG and FFA) were significantly (P<0.05) increased and the level of PL was significantly (P<0.05) decreased in L-NAME hypertensive rats when compared to control rats. Treatment with D-carvone significantly (P<0.05) declined the levels of TC, TG and FFA, and increased the level of PL in L-NAME hypertensive rats.

Table 1. Effect of D-carvone on lipid profile in aorta of control and L-NAME induced hypertensive rats.

Parameter		Control	Control+D-C	L-NAME	L-NAME+D-C
TC	Aorta	3.82 $\pm$ 0.22	2.99 $\pm$ 0.16	5.97 $\pm$ 0.41*	4.12 $\pm$ 0.21#
TG	Aorta	2.79 $\pm$ 0.15	2.83 $\pm$ 0.22	4.24 $\pm$ 0.45*	3.02 $\pm$ 0.22#
FFA	Aorta	3.82 $\pm$ 0.32	3.99 $\pm$ 0.26	5.26 $\pm$ 0.50*	4.02 $\pm$ 0.32#
PL	Aorta	5.43 $\pm$ 0.27	5.76 $\pm$ 0.29	3.66 $\pm$ 0.22*	5.96 $\pm$ 0.56#

Columns are mean $\pm$ S.D. for six rats in each group. Data were analyzed by one-way ANOVA followed by Duncan's multiple range test (DMRT). * $P < 0.05$ compared with the control. # $P < 0.05$ compared with the L-NAME.

3.3. Effects of D-carvone on nitric oxide metabolites

Fig. 3 depicts the levels of nitric oxide metabolites (nitrite and nitrate) in plasma of control and L-NAME induced hypertensive rats. L-NAME induced hypertensive rats had significantly ($P < 0.05$) decreased levels of total nitrite and nitrate levels in plasma and treatment with D-carvone significantly ($P < 0.05$) elevated the levels of nitric oxide metabolites.

Fig. 3. Effect of D-carvone on plasma NO concentration in control and L-NAME induced hypertensive rats.

Columns are mean $\pm$ S.D. for six rats in each group. Data were analyzed by one-way ANOVA followed by Duncan's multiple range test (DMRT). * $P < 0.05$ compared with the control. # $P < 0.05$ compared with the L-NAME.

3.4. Effect of D-carvone on enzymatic antioxidants

Table 2 shows the activities of superoxide dismutase, catalase and glutathione peroxidase in erythrocytes of control and L-NAME hypertensive rats. The activities of these enzymatic antioxidants were significantly ($P < 0.05$) decreased in L-NAME hypertensive rats. Treatment with D-carvone significantly ($P < 0.05$) restored the activity of these enzymatic antioxidants in erythrocytes of L-NAME hypertensive rats.

Table 2. Effect of D-carvone on SOD, CAT and GP_x in erythrocytes of control and L-NAME induced hypertensive rats.

Parameter		Control	Control+D-C	L-NAME	L-NAME+D-C
Superoxide dismutase	Erythrocyte (U ^a /mgHb)	7.11 ± 0.52	7.14 ± 0.63	3.38 ± 0.37 [*]	6.15 ± 0.38 [#]
Catalase	Erythrocyte (U ^b /mg Hb)	173.20 ± 9.57	174.05 ± 9.62	99.77 ± 6.96 [*]	158.03 ± 7.84 [#]
Glutathione peroxidase	Erythrocyte (U ^c /mg Hb)	14.12 ± 0.84	14.43 ± 0.88	6.98 ± 0.59 [*]	12.05 ± 0.49 [#]

U^a, enzyme concentration required to inhibit the chromogen produced by 50% in one minute under standard condition. U^b, μ mole of H₂O₂ consumed/minute. U^c, μ g of GSH utilized/minute. Values are mean $\pm$ S.D. for six rats in each group. Data were analyzed by one-way ANOVA followed by Duncan's multiple range test (DMRT). ^{*}P<0.05 compared with the control. [#] P<0.05 compared with the L-NAME.

4. DISCUSSION

The main vaso-relaxing factor produced by endothelial cells is nitric oxide. It is synthesized from L-arginine by the action of endothelial nitric oxide synthase and is important for the regulation of blood pressure (Moncada and Higgs, 1993). Arterial hypertension, an important risk factor of cardiovascular diseases, is characterized by production of excessive reactive oxygen species interacting with NO and reducing its bioavailability; oxidation of NO to peroxynitrite by reactive oxygen species induces oxidative stress (De Gennaro Colonna et al., 2005). Chronic inhibition of NO produces volume-dependent elevation of blood pressure; and its physiological and pathological characteristics resemble essential hypertension (Attia et al., 2001). Besides, it is well established that acute inhibition of NO biosynthesis by in vivo administration of L -NAME, an L-arginine analog, leads to arterial hypertension and vasoconstriction (Attia et al., 2001). Several studies related to experimental hypertension showed that an increase in arterial blood pressure reduces circulatory nitric oxide, which reflects the role of arginine–nitric oxide in the pathophysiology of hypertension (Dryden et al., 2005). Our findings show that L-NAME-treated rats showed significantly increased heart rate and water intake. Treatment with D-carvone significantly reduced the heart rate and water intake that may be due to increasing the bioavailability of nitric oxide and antioxidant actions of D-carvone (Johri, 2011).

The presence of high BP and hyperlipidemia is so common in hypertension that many have argued that the high BP itself may play a role in altering lipid metabolism, resulting in abnormalities (Friedwald et al., 1972a,b). The blockade of NO synthase by L-NAME seems to be involved in lipid metabolism alterations: increases serum/plasma cholesterol levels in rats (Khedara et al., 1996). Hypercholesterolemia and hypertriglyceridemia were seen in nitric oxide-deficient rats which might be due to increased mobilization of lipids from liver and kidney tissues (Saravana kumar et al., 2010; Saravana kumar and Raja, 2012). Elevated total

cholesterol (TC) levels augment the risk of cardiovascular disease associated with hypertension. Elevated cholesterol levels predispose to a condition known as hypercholesterolemia. Large epidemiologic studies have demonstrated that subjects with hypertension have a marked increase in the prevalence of hypercholesterolemia (Yang et al., 2011). The observed increase in TGs might be due to a decrease in the activity of lipoprotein lipase, resulting in decreased uptake of TGs from the circulation (Casazza et al., 2009).

Hypertension frequently coincides with elevated levels of triglycerides (TGs). Very low density lipoprotein-cholesterol (VLDL-C) is the major transport vehicle for the TGs from the liver to extra hepatic tissues, whereas low density lipoprotein-cholesterol (LDL-C) is not secreted as such the liver; rather, it seems to be formed from VLDL-C after partial removal of TGs by lipoprotein lipase (Mayes, 1997). Fatty acids play a key role in the formation and maintenance of all cells and PL are the major structural components of intracellular membranes in all living organisms. Abnormalities in fatty acids and phospholipid metabolism are important in the pathogenesis of cell membrane dysfunction (Saravana kumar et al., 2010). Our results showed a decrease in the levels of TC, TG, FFA and increase in the level of PL in L-NAME hypertensive rats after treatment with D-carvone.

Nitric oxide synthesized by endothelial NO synthase (eNOS) is a major regulator of the vascular tone. Arterial hypertension, an important risk factor of cardiovascular diseases, is characterized by production of extra amount of reactive oxygen species (ROS) interacting with NO and reducing its bioavailability; oxidation of NO to peroxynitrite by ROS induces oxidative stress (De Gennaro Colonna et al., 2005). In addition, decrease in eNOS activity leads to a decrease in NO bioavailability (Rybka et al., 2011). It suggests that dysfunction of NO pathway in hypertensive subjects is a consequence rather than a cause of elevated blood pressure (Boulanger, 1999). In addition, NO has been identified as important in other cellular events, such as a vascular smooth muscle cell proliferation (Nguelefack-Mbuyoa et al., 2008). In this study we demonstrated that treatment with chronic inhibition of NOS by L-NAME rats significantly decreased plasma NOx levels. Treatment with D-carvone improved plasma NOx levels in L-NAME rats, effects that may be attributed to its antioxidant properties.

Superoxide dismutase, catalase and glutathione peroxidase balance together to eliminate reactive oxygen species, and small deviations in physiological concentrations may have a dramatic effect on the resistance of cellular lipids, proteins, and DNA to oxidative damage (Mates and Sanchez-Jimenez, 1999). SOD plays an important role in scavenging superoxide anion, which is the initial free radical, among the oxygen radicals. Catalase prevents oxidative hazard by catalyzing the formation of water and oxygen from hydrogen peroxide (Rajeshkumar and Kuttan, 2003). GPx offers protection to the cellular and subcellular membranes from the peroxidative damage by eliminating hydrogen peroxide by utilizing reduced glutathione and H_2O_2 as substrates to yield H_2O and oxidized glutathione and its declined activity may be due to the reduced availability of GSH (Li et al., 2012). In consistency with the previous reports, L-NAME induced hypertensive rats showed significantly depleted levels of antioxidant enzymes in tissues (Kumar et al., 2011; Saravanakumar and Raja, 2011). Administration of D-carvone, improved the activities of enzymatic antioxidants in L-NAME induced hypertensive rats. The increased activities of these enzymic antioxidants in D-carvone treated rats might be due to the increased nitric oxide metabolites which could exert a beneficial action against pathophysiological alterations caused by superoxide anion and hydroxyl radicals.

Major findings from the present study confirmed that D-carvone supplementation could effectively prevent the development of hyperlipidemia in L-NAME rats. Our findings also illustrate that the aorta damage was ameliorated by D-carvone supplementation.
