Keywords: Soybean, Salt stress, Glutathione, Cyanobacteria, Antioxidant defense systems, Nutrients, Growth

Abstract. Salt stress restricts plant performance by disrupting various physio-biochemical processes like photosynthesis. Plants growing in saline substrates show deficiencies in absorption of some essential elements due to the presence of excessive sodium (Na^+) in the rhizosphere, which antagonizes beneficial cations and causing toxicity in metabolism. Cyanobacteria (CB; a natural biofertilizer) play a fundamental role in building-up soil fertility, thus increasing plant performance. Glutathione (GSH) is a well-known antioxidant, which contributes to increase salt tolerance in the plant. This work was conducted as a pot experiment (sand culture) in 2017 to study the combined effect of CB, applied as seed inoculation, and GSH, applied as foliar spray, on growth, pods and seed yields, the contents of antioxidants, osmoprotectants, and nutrients, and the antioxidative enzymes activities of soybean (*Glycine max* L., cv. Giza 111) plants grown under saline conditions. At fourth leaf stage (21 days after sowing; DAS), CB-pretreated seedlings were supplemented with NaCl (150 mM) along with Hoagland's nutrient solution, and at the same time seedlings were sprayed with 1 mM GSH. Samples were taken at 60 DAS to assess morphological, physio-biochemical and antioxidant defense systems attributes. Results showed that the integrative application of CB and GSH under saline conditions was effective in improving significantly the growth characteristics, yield components, photosynthetic efficiency (pigments contents and chlorophyll fluorescence), membrane stability index, relative water content, contents of soluble sugars, free proline, ascorbic acid, glutathione, α -tocopherol, and protein, and activities of superoxide dismutase, catalase, and guaiacol peroxidase. The contents of macronutrients (N, P, K^+ , and Ca^{2+}) were also increased significantly in *Glycine max* plants compared to the stressed control. In contrast, Na^+ content and electrolyte leakage were significantly reduced. Our results recommend using the combined CB (as seed inoculation) and GSH (as foliar spray) application for soybean plants to grow well under saline conditions.

Introduction

Soybean is an important nutritional and medicinal crop. Its oil is classified as polyunsaturated, including approximately 24% monounsaturated and 61% polyunsaturated oil, besides 15% saturated oil. Approximately 53.2% from the polyunsaturated oil is linoleic acid, whereas linolenic acid comprises approximately 7.8%. This gives advantages to regulate plasma lipid and eicosanoids biosynthesis based on the results obtained from many studies of human clinical trials. These clinical trials have reported that soybean oil effectively lower the serum cholesterol, and likely it can be used as a potential hypocholesterolemic agent if it used as a dietary fat and helps prevent atherosclerosis and heart diseases [1].

Under salinity stress, decrease in plant growth is interlinked, usually, with a diverse group of physio-biochemical and molecular characteristics [2, 3]. Plant response to salt stress is very complex and varies from species to species and even from cultivar to cultivar within the same

species [4, 5]. Most plants exposed to saline regimes show alterations in different physio-biochemical attributes and antioxidant defense (non-enzymatic and enzymatic systems [6-9]). The most common phyio-biochemical attributes affected by salinity stress in different plants include protein synthesis and phytohormone regulation [10], photosynthetic capacity [9, 11], water relations [12], and activity of enzymatic antioxidants and level of inorganic nutrients [7-9, 12, 13]. Under salt stress, reactive species of oxygen (ROS) are overproduced in plants in response to stress conditions as one of the key secondary effects of salinity stress on plants [13, 14]. These ROS cause damage to cellular ultrastructure and organic compound as well as impair a variety of metabolic process reactions [14, 15]. Under salt stress, plants show more negative water potential that negatively affects plant growth [16]. In [17], a significant reduction in lipid peroxidation and glutathione reductase activity is reported, while superoxide dismutase and catalase activities as well as proline contents are increased in pistachio seedling under varying saline regimes. It has generally been concluded that a large number of crops are sensitive to salt stress during the durations of seed germination and seedling establishment [18].

Cyanobacteria (CB) are considered as a natural biofertilizer that play a fundamental role in soil maintenance and soil fertility buildup. It has been concluded that CB increase plant performances [19, 20], and raise soil water holding capacity *via* CB jelly structure [21], and decrease the level of soil salinity [22]. In addition, Glutathione (GSH) is an antioxidant, a tripeptide (α -glutamyl cysteinylglycine) that has been detected in all compartments of plant cell. GSH is an essential thiol antioxidant as well as a scavenger of reactive electrophilic compounds [23]. It has a gamma peptide linkage between the cysteine group and the $-\text{COOH}$ group of the side-chain of glutamate. It prevents ROS damages to important components of cells [24]. In plants, GSH is functioned in the ascorbate-glutathione cycle to maintain redox homeostasis in plant cells in response to oxidative stress. GSH is functioned in this cycle by dehydroascorbate reductase (DHAR) for regenerating the ascorbate that scavenges H_2O_2 , and it is converted to the oxidized form (GSSG) that is, then, regenerated by GSH-reductase [25, 26].

Therefore, this work was carried out to evaluate the potential beneficial effects of CB, used as seed inoculation, in combination with GSH, used as foliar spray, on growth, pods and seed yields, the contents of osmoprotectants, antioxidants, and nutrients, as well as on the activity of some antioxidative enzymes of soybean (*Glycine max* L., cv. Giza 111) plants grown on a sand culture under salt stress (150 mM NaCl).

Materials and Methods

Growth condition and experimental design

A pot experiment was conducted (repeated three times) in a greenhouse at the Farm of the Fayoum University, south west Giza, Egypt during the summer season 2017. Soybean (*Glycine max* L., cv. Giza 111) seed were purchased from the Agriculture Research Center, Giza, Egypt and sown on the first of May. Seed were surface sterilized using 0.1% HgCl_2 for 60 sec, and then washed several times using sterilize-deionized water. Plastic pots (50-cm diameter, 40-cm depth) were filled with equal amounts of sand that was previously washed several times with commercial acid to remove all ions, and then washed several times with distilled water to remove the acid. Each pot was received 6 seed, and then pots ($n = 90$) were arranged in a completely randomized design a greenhouse for growing plants (repeated 3 times). Sand soil pH was adjusted back to the control pH (6.0–6.2) with diluted H_2SO_4 .

Irrigation and treatments

The Hoagland's nutrient solution ($\frac{1}{2}$ -strength) [27] was supplied to all pots at 100% field capacity (FC) every 2 days up to 20 days, at which plants were thinned to three in each pot. At the fourth leaf stage (21 days after sowing; DAS), seedlings were supplemented with NaCl at a level of 150 mM along with the nutrient solution. Seedlings were sprayed with deionized water (control) or 1 mM GSH beginning at the same time in which they received the salt treatment. Spraying of GSH on the foliage of plants was conducted to run off, two times; 21 and 35 DAS. Tween-20 was added (few drops) to the solution as a wetting agent. Supplementation of plants with NaCl was stopped at

60 DAS. The selection of the GSH concentration (1 mM) and NaCl level (150 mM) was based on a small scale preliminary study (data not shown). Where, 1 mM GSH generated the best response and NaCl at the concentration above 150 mM was lethal.

Collection of samples

Sixty-day-old seedlings were randomly taken from each treatment for various growth, physio-biochemical and antioxidative defense systems determinations. At harvesting (120 DAS), pods on all plants of each treatment were collected to assess pods and seeds yields components. Samples were divided into 3 groups as follows: Group A was used for measuring growth parameters, yield and yield components, and nutrient contents. Group B was the plant shoot system and new leaves that were immediately weighed, frozen with liquid N and stored in a deep freezer at -20°C up to use for extraction and assaying leaf enzymatic protein and enzymatic antioxidants (superoxide dismutase; SOD, catalase: CAT, and guaiacol peroxidase; GPOX). And group C was new fresh leaves that were used for assessing photosynthetic pigments, photosynthetic efficiency, free proline content, total soluble sugars, ascorbic acid, glutathione, α -tocopherol, relative water content, electrolyte leakage and membrane stability index.

Measurements of growth characteristics, and yield and yield components

Plant samples ($n = 3$) were separated to measure shoot length (cm), plant leaf number, plant leaf area (dm^2), and shoot dry weights (g). Shoots were dried at 70°C for 48 h or until the constant weight. At harvest, pods on all plants were collected from each treatment and plant pod number, 100-seed weight (g) and plant dry seed weight (g), seed protein and seed oil contents were also assessed.

Measurements of physio-biochemical attributes

Photosynthetic Pigments and Photosynthetic Efficiency

Contents (mg g^{-1} fresh weight; FW) of chlorophylls and carotenoids were estimated using the method in [28]. The methods in [29, 30] were used to assess photosynthetic efficiency using fully expanded mature leaves on corresponding plants that were conducted at the same time of two sunny days. Chlorophyll fluorescence was assessed measuring maximum quantum yield of PSII Fv/Fm (by a Handy Portable fluorometer, Hansatech Instruments Ltd, Kings Lynn, UK)) using the formulae; $\text{Fv/Fm} = (\text{Fm} - \text{F}_0)/\text{Fm}$. In addition, performance index (PI) was calculated based on equal absorption (PIABS).

Free Proline and Total Soluble Sugars (TSS) Contents

Using the method in [31], proline content was extracted (using 10 ml of 3%, v/v, sulphosalicylic acid) and determined, using freshly prepared acid-ninhydrin solution, in toluene phases collected carefully by reading the absorbance at 520 nm against a standard proline curve.

Content of TSS was measured after extraction by 96% (v/v) ethanol using the method in [32]. TSS content was determined in the ethanolic extract reacted with freshly-prepared anthrone reagent by reading the absorbance at 625 nm using a Bausch and Lomb-2000 Spectronic Spectrophotometer (Thermo Spectronic, Cambridge, UK).

Determinations of membrane stability index (MSI), electrolyte leakage (EL), and relative water content (RWC)

MSI (%), EL (%), and RWC (%) were determined using the methods described in [33, 34] using the fully expanded corresponding leaves, and the following formula, respectively:

$$\text{MSI (\%)} = [1 - (C_1 / C_2)] \times 100$$

$$\text{EL (\%)} = [(C_b - C_a) / C_c] \times 100$$

$$\text{RWC (\%)} = [(\text{FM} - \text{DM}) / (\text{TM} - \text{DM})] \times 100$$

Determination of non-enzymatic antioxidants contents

The methods detailed in [35, 36, 37, 38] were followed to assess the contents of ascorbic acid (AsA), glutathione (GSH), and α -tocopherol (α -TOC).

The AsA content was homogenized using fresh leaf sample in 5% (w/v) TCA. The resulted supernatant was used to assess the AsA content in the reaction mixture (10 mM DTT, 0.2 M phosphate buffer (pH 7.4), 0.5% NEM, 10% TCA, 42% H₃PO₄, 4% 2,2'-dipyridyl and 3% FeCl₃).

The GSH content was extracted from fresh leaves in buffer solution (2% sulfosalicylic acid, 1 mM Na₂EDTA and 0.15% AsA). The resulted supernatant was used to measure the GSH content by GSH assay kit (Sigma Chemical Co., USA).

The α -TOC content was determined using R-TOC and standard solutions (20–200 μ g/ml) prepared using stock solution (50 mg/100 ml n-hexane). Samples were prepared, saponified, sliced, dried, homogenized, and suspended using water in a conical flask (0.5–1 L). After adding AsA, saponification was done and water was then added to reach the ethanol/water ratio to 0.3. Then, n-hexane/ethyl acetate [9:1 (3 $\times$ 100 ml)] was added. The mixtures were extracted three times, and the organic phases were then combined, washed, and filtered. After filtration and evaporation to dryness, residues were dissolved in n-hexane (HPLC grade) and cool-stored (at –20°C). The α -TOC was assessed using a HPLC system with a Waters Bondapak C₁₈ reverse-phase column. Mobile phase (94 methanol: 6 water) was used at the flow rate of 1.5 ml min^{–1} and UV detector was set at 292 nm.

Assaying the activities of enzymes

One g of fresh leaves was used to extract the antioxidant enzymes. Filtration and homogenization in liquid N₂ with phosphate buffer (0.05 M, pH 7.0) that contained EDTA (100 mM) and PVP (1%) were conducted for the biomass at 4 °C. The extraction buffer: leaf biomass (v/w) proportion was 2:1, respectively. Centrifugation (15,000 $\times$ g) was done for the homogenate at 4 °C for 10 min. By using phosphate buffer, the obtained supernatant was dialyzed overnight. Enzyme activities were performed, and protein content was determined in the homogenate according to [39].

Activities of superoxide dismutase (SOD; EC.1.15.1.1), catalase (CAT; EC. 1.11.1.6), and guaiacol peroxidase (GPOX; EC.1.11.1.7)

The activity of SOD was assayed as described in the method in [40]. The enzyme ability to inhibit the photochemical reduction of nitroblue tetrazolium (NBT) indicates to the enzyme activity and the change in the absorbance was read at 560 nm. Reaction mixture was consisted of phosphate buffer (25 mM, pH 7.8), NBT (65 μ M), riboflavin (2 μ M), TEMED, and the enzyme extract. This reaction mixture was exposed to light (350 μ mol m^{–2} s^{–1}) for 15 min. The enzyme activity was expressed as nmol of H₂O₂ mg^{–1} soluble protein min^{–1}.

The CAT activity was assayed as described in the method in [41]. The decomposition rate of H₂O₂ read at 240 nm was recorded spectrophotometrically and calculated by using the molar extension coefficient by using $\epsilon = 45.2 \text{ mM}^{-1} \text{ cm}^{-1}$. Reaction mixture was consisted of phosphate buffer, H₂O₂ (0.1 mM) and the enzyme extract. One unit of catalase activity was presumed as the amount of enzyme, which decomposed 1 nmol of H₂O₂ mg^{–1} soluble protein min^{–1} at 30 °C.

Guaiacol peroxidase activity was determined according to the method in [42].

Leaf protein content

A weight of 0.5 g fresh leaf tissue (FW) was homogenized using 3 ml potassium phosphate buffer (0.1 M) in a pre-chilled pestle and mortar. The homogenate was centrifuged (15,000 $\times$ g) for 20 min. The resulted supernatant was used to assess the content of protein and the activities of antioxidant enzymes. Protein content was estimated as described in [39].

Statistical analysis

The obtained data were statistically analyzed, and the comparisons among all means of all treatments were perfected by using the procedure of Least Significant Differences (LSD) at $P \leq 0.05$ level as outlined in [43].

Results

Effect of cyanobacteria (CB) and glutathione (GSH) applications on growth characteristics of salt-stressed *Glycine max* L. plant

Data cited in Table 1 show the effect of CB seed inoculation and GSH foliar application (1.0 mM) on growth characteristics of *Glycine max* L. plants grown under saline (150 mM NaCl) conditions. Data revealed that shoot length, No. of leaves plant⁻¹, leaf area plant⁻¹, and shoot dry weight were significantly decreased (from 52.4 to 30.5 cm, 24.5 to 13.2, from 11.8 to 6.2 dm², and from 8.94 to 4.23 g, respectively) with salinity treatment compared to the control, while the decrease was improved (from 30.5 to 40.7 or 37.2 cm, 13.2 to 20.8 or 17.8, 6.2 to 10.3 or 8.4 dm², and from 4.23 to 7.68 or 6.41 g, respectively) with CB or GSH treatment under NaCl stress. However, the combined treatment of CB + GSH further improved shoot length (to 49.9 cm, 23.6, 11.6 dm², and 8.79 g, respectively) under salinity stress compared to the control.

Table 1. Effect of seed treatment with CB and foliar treatment with GSH (1.0 mM) on growth characteristics of salt-stressed *Glycine max* L. plant

Treatments	Parameters			
	Shoot length (cm)	Number of leaves plant ⁻¹	Leaf area plant ⁻¹ (dm ²)	Shoot dry weight (g)
Control	52.4±4.2a	24.5±2.6a	11.8±1.9a	8.94±0.96a
Salinity (S)	30.5±3.1d	13.2±1.5d	6.2±1.2d	4.23±0.53d
S+CB	40.7±3.7b	20.8±2.4b	10.3±1.8b	7.68±0.83b

Effect of cyanobacteria (CB) and glutathione (GSH) applications on pod and seed yields of salt-stressed *Glycine max* L. plant

Data presented in Table 2 show that effect of CB seed inoculation and GSH foliar application (1.0 mM) on pod and seed yields of *Glycine max* L. plants grown under saline (150 mM NaCl) conditions. Data revealed that pod number plant⁻¹ was decreased (from 10.6 to 6.4) under salt stress compared to control, while its decrease was improved (from 6.4 to 8.0 or 7.1, respectively) with CB or GSH treatment. However, this parameter was further increased (to 10.2) with the combined CB + GSH treatment. For 100-seed weight parameter, it was reduced (from 10.7 to 5.9 g) under salt stress treatment compared to control, but its reduction was improved (from 5.9 to 8.4 or 8.0 g, respectively) with CB or GSH treatment, and further improved (to 10.4 g) with the combined CB + GSH treatment. In similar, dry seed weight plant⁻¹ character was decreased (from 10.0 to 5.4 g) with NaCl salt treatment compared with control. However, its decrease was improved (from 5.4 to 8.1 or 7.3 g, respectively), and was further increased (to 9.7 g) with the combined treatment of CB + GSH compared to control. For seed protein content, it was decreased (from 31.2 to 23.8 %) under salt stress compared to control, but its reduction was improved (from 23.8 % to 25.9 or 24.4 %, respectively) with CB or GSH treatment, and was further improved (to 30.8 %) with the combined CB + GSH treatment compared to control. For seed oil content, it was reduced (from 21.6 to 15.3 %) under salinity stress compared to the control, but the decrease was improved (from 15.3 % to 18.8 or 16.9 %, respectively) with the treatment of CB or GSH. The combined treatment of CB + GSH further improved this parameter (to 21.5 %) compared to control.

Table 2. Effect of seed treatment with CB and foliar treatment with GSH (1.0 mM) on pod and seed yields of salt-stressed *Glycine max* L. plant

Treatments	Parameters				
	Pods No. plant ⁻¹	100-seed weight (g)	Dry seed weight plant ⁻¹ (g)	Seed protein (%)	Seed oil (%)
Control	10.6±1.9a	10.7±1.4a	10.0±1.2a	31.2±1.5a	21.6±1.3a
Salinity (S)	6.4±0.8d	5.9±1.0c	5.4±0.6d	23.8±1.2c	15.3±1.0d

Effect of cyanobacteria (CB) and glutathione (GSH) applications on leaf pigment contents and chlorophyll fluorescence of salt-stressed *Glycine max* L. plant

Table 3 shows that total chlorophylls and carotenoids contents were decreased (from 2.12 to 0.90 and from 0.41 to 0.27, respectively) with NaCl salinity (150 mM) compared with control. However, their reductions were improved (from 0.90 to 1.58 or 1.30, and from 0.27 to 0.31 or 0.27, respectively) with CB or GSH treatment, and were further enhanced (to 2.05 and to 0.40) under the combined treatment of CB + GSH compared to control. Also, Fv/Fm and PI were decreased (from 84.3 to 59.4, and from 73.7 to 52.3) with salt stress treatment compared to control, while their decrease were improved (from 59.4 to 74.5 or 67.7, and 52.3 to 64.5 or 60.4, respectively) with CB or GSH treatment, and were further increased (to 84.0 and to 73.0) with the combined treatment of CB + GSH compared with control.

Table 3. Effect of seed treatment with CB and foliar treatment with GSH (1.0 mM) on leaf photosynthetic pigments (mg g⁻¹ fresh weight) and chlorophyll fluorescence of salt-stressed *Glycine max* L. plant

Treatments	Parameters

Effect of cyanobacteria (CB) and glutathione (GSH) applications on relative water content (RWC), leakage of electrolytes (EL) and index of membrane stability (MSI) of leaves of salt-stressed *Glycine max* L. plant

Data presented in Table 4 show that RWC (%) and MSI (%) were decreased (from 81.3 to 59.8 %, and from 76.0 % to 51.2 %, respectively) with treatment of NaCl salinity (150 mM) compared with control, while their decreases were improved (from 59.8% to 74.2 or 67.7 %, and from 51.2% to 68.7 or 62.4%, respectively) with CB or GSH treatment, and were further enhanced (to 81.4%, and to 74.8%, respectively) compared to the control. EL (%) parameter was, in contrast, increased with salinity treatment, while it was decreased with CB or GSH treatment, and was further reduced with the combined CB + GSH treatment compared to control.

Table 4. Effect of seed treatment with CB and foliar treatment with GSH (1.0 mM) on leaf relative water content (RWC, %), electrolyte leakage (EL, %) and membrane stability index (MSI, %) of salt-stressed *Glycine max* L. plant

Treatments	Parameters		
	RWC (%)	EL (%)	MSI (%)
Control	81.3±4.8a	7.9±0.6d	76.0±6.3a
Salinity (S)	59.8±2.7d	15.8±0.9a	51.2±4.6d

Effect of cyanobacteria (CB) and glutathione (GSH) applications on contents of soluble sugars, proline, ascorbate (AsA), glutathione (GSH), and α -tocopherol (α -TOC) of salt-stressed *Glycine max* L. plant

Data in Table 5 show that leaf contents of total soluble sugars, free proline, AsA, GSH, and TOC of *Glycine max* L. plants were significantly decreased under the treatment of NaCl-salinity (150 mM) compared with control. While, the decreases in these parameters contents were significantly improved with CB or GSH treatment, and were further improved compared to control.

Table 5. Effect of seed treatment with CB and foliar treatment with GSH (1.0 mM) on leaf contents of total soluble sugars, free proline, AsA, GSH and α -TOC of salt-stressed *Glycine max* L. plant

Treatments	Parameters				
	Soluble sugars (mg g ⁻¹ DW)	Free proline (µg g ⁻¹ DW)	AsA (µmol g ⁻¹ DW)	GSH (µmol g ⁻¹ DW)	TOC (µg g ⁻¹ DW)
Control	3.27±0.11c	251±6c	1.33±0.02c	1.22±0.01c	38.4±0.21c

Effect of cyanobacteria (CB) and glutathione (GSH) applications on content of enzymatic protein and enzyme activities of superoxide dismutase (SOD), catalase (CAT) and guaiacol peroxidase (GPOX) in salt-stressed *Glycine max* L. plant

Data presented in Table 6 show the effect of CB seed inoculation and GSH (1 mM) foliar application on leaf content of enzymatic protein and leaf enzymatic activities of SOD, CAT and GPOX of *Glycine max* L. plants grown under saline conditions (150 mM NaCl). The activities of SOD, CAT, and GPOX were significantly increased with treatment of NaCl salinity compared with control, and these enzymes activities were further improved with CB or GSH treatment, and were excessive further improved with the combined CB + GSH treatment compared to control. In contrast, leaf enzymatic protein content was decreased with salinity treatment, while it was improved with CB or GSH treatment, and was further increased with the combined CB + GSH treatment compared to control.

Table 6. Effect of seed treatment with CB and foliar treatment with GSH (1.0 mM) on leaf enzymatic protein and the activities of enzymatic antioxidants (superoxide dismutase; SOD, catalase; CAT and guaiacol peroxidase; GPOX) of salt-stressed *Glycine max* L. plant

Treatments	Parameters			
	Leaf protein (mmol g ⁻¹ FW)	SOD (μmol mg ⁻¹ protein)	CAT (μmol mg ⁻¹ protein)	GPOX (μmol mg ⁻¹ protein)

Effect of cyanobacteria (CB) and glutathione (GSH) applications on leaf macro-nutrients (N, P, K⁺, and Ca²⁺) and sodium (Na⁺) contents in salt-stressed *Glycine max* L. plant

Data cited in Table 7 reveal the effect of CB seed inoculation and GSH (1 mM) foliar application on leaf contents of macro-nutrients (N, P, K⁺ and Ca²⁺) and sodium (Na⁺) of *Glycine max* L. plant grown under saline conditions (150 mM NaCl). Contents of N, P, K⁺ and Ca²⁺ were significantly decreased with treatment of NaCl salinity compared with control, and these macro-nutrient contents were improved with CB or GSH treatment, and were further improved with the combined CB + GSH treatment compared to control. In contrast, leaf content of Na⁺ was increased with salinity treatment, while it was significantly decreased with CB or GSH treatment, and was further decreased with the combined CB + GSH treatment compared to control.

Table 7. Effect of seed treatment with CB and foliar treatment with GSH (1.0 mM) on the contents of macro-nutrients (N, P, K⁺, and Ca²⁺) and sodium (Na⁺) of salt-stressed *Glycine max* L. plant

Treatments	Parameters				
	N (%)	P (%)	K ⁺ (%)	Ca ²⁺ (%)	Na ⁺ (%)
Control	3.24±0.07a	0.35±0.02a	3.43±0.07a	1.29±0.02a	0.40±0.02d
Salinity (S)	1.88±0.05d	0.21±0.01d	1.91±0.02d	0.87±0.01d	0.92±0.05a
S+CB	2.66±0.06b	0.28±0.01b	2.68±0.05b	1.17±0.02b	0.56±0.03c
S+GSH	2.39±0.06c	0.24±0.01c	2.38±0.05c	0.98±0.01c	0.64±0.03b
S+CB+GSH	3.21±0.07a	0.34±0.02a	3.38±0.08a	1.25±0.02a	0.41±0.02d

Values are means of 5 readings. Means in each column followed by different letters are different significantly at $p \leq 0.05$ performed by Duncan's Multiple Range Test.

Discussion

As awaited, soybean plants pretreated with a bio-fertilizer like cyanobacteria (CB) in integration with the antioxidant glutathione (GSH) foliar application conferred higher dry matter than stressed plants without treatments. The increased plant dry weight was obtained as a result of increase in other growth parameters, especially plant height, leaves number, and leaves area. This may also be attributed to the increase obtained of the efficiency of photosynthesis (measured in terms of leaf pigments; chlorophylls and carotenoids contents, as well as chlorophyll fluorescence; Fv/Fm and PI), which are supported by improved activities of (non-enzymatic and enzymatic) antioxidant defence systems by this integrative treatment (Tables 2–6). The beneficial effects of CB may be due to supplying plants by various nutrients, besides lowering soil pH that may facilitate soil nutrient availability for plants and their physiological processes like carbohydrate use and photosynthetic activity. Therefore, CB improve chemical characteristics of soil and enhance biological and physical characters that represent favourable factors for root development [44]. The report [45] showed that higher accumulation of salts in soil shows a lower water potential zone in soil. This makes the soil to be increasingly difficult for acquiring both water and nutrients by plants.

Therefore, water deficiency (in terms of "physiological drought") is generated by salt stress. As considered as a key marker for studies of salt stress, relative water content (RWC) measurement is a generic method utilized to assess water balance in plant leaf during water deficient durations. RWC assesses the amount of water (%) found in a leaf tissue as a hold fraction of the total volumetric water at cell full turgor. By maintaining cell RWC, permanence of metabolic activity is allowed by osmotic adjustments and other characters of adaptation to salt and/or drought stress [46]. Using different CB types significantly increased RWC, which may be attributed to accompany raise in hydraulic nature of branch root crosses that facilitate the radial water flow, and/or root morphology changes (i.e., root branching and its dry weight) [44]. Also, CB maintain stability of membrane structure (membrane stability index; MSI) under stress [20]. Cytoplasmic membranes of cells are an important one of the first objects of various unfavourable environmental factors. It has been, generally, accepted that cell membrane maintenance (for their integrity and stability) is one of the major targets for performing higher plant performance (acceptable growth and yields) [20]. Highest RWC and MSI, and lowest leakage of inorganic ions were observed with the integrative CB + GSH treatment compared to the individual treatments including the control (Table 4).

The beneficial impacts of the combined treatment of CB + GSH could be elucidated on the basis of the improvement of soil physical, chemical and biological characters occurred by CB, in addition to that GSH forms an important part of plant response to abiotic stress, including salinity [20]. It has been reported that GSH alleviates and repairs damages generated by reactive species of oxygen (ROS; $O_2^{\cdot-}$, 1O_2 , H_2O_2 , and $OH^{\cdot-}$). It, therefore, enables plants to adopt and/or develop a complex antioxidant defense system to effectively raise cellular defenses against oxidative stress induced by salt stress [47-49]. GSH application as an integrative treatment with CB conferred best results for soybean yield (Table 2) compared to the individual treatments including the control. This result attribute perhaps to the integrative roles of CB in repairing the rhizosphere; roots growth zone and GSH in alleviating and repairing the damages generated by ROS under salt stress [20].

It has been concluded that carotenoids are implicated in photosynthetic apparatus protection against photoinhibitory damages caused by 1O_2 that is producing by the excited triplet state of chlorophyll [20, 50]. Carotenoids deactivate 1O_2 directly and quench the excited triplet state of chlorophyll, therefore, reducing 1O_2 formation indirectly. Closure of stomata due to osmotic stress or salt induced photosynthetic apparatus damage causes a reduction in chlorophylls content of mungbean leaves [45]. Plants pretreated with CB and then treated with GSH (an integrative treatment) conferred highest content of leaf photosynthetic pigments compared to other individual treatments (Table 3). CB can stimulate plant growth substances to improve leaf chlorophylls contents [51]. In this study, CB or CB + GSH treatments increased total chlorophyll and carotenoid contents (Table 3). In CB, salt stress stimulates both respiration rate and PS1 activity, and also impairs the photosynthetic rate [52]. The overall performance index (PI) shows a single multiparametric expression, which combines all three steps of independent photosynthetic functions; the reaction centres density in the chlorophyll pool, trapped excitation energy, and its conversion to electron transport [53]. Values of PI and Fv/Fm (Table 3) indicate that photosynthetic performance due to CB or CB + GSH significantly increased under salt stress. This indicates a positive effect of the bio-fertilizer CB on the plant photosynthetic machinery.

Accumulated contents of free proline, soluble sugars, GSH, AsA, and α -TOC under salt stress preserve plant cells by balancing of osmotic strength of cytosol with that of vacuole and external environment [54]. In addition, free proline, as an important physiological index for plant response to salt stress, possesses a dual role in improving the tolerance to salt stress due to its ability to act in a similar way to the enzyme peroxidase and to scavenge ROS [50, 55]. Application of CB increased the accumulation of proline in soybean plants (Table 5). Higher proline content is favourable to plants salt stress due to it participates in the leaf osmotic potential and, thus, in leaf osmotic adjustment [50]. In the current study, soluble sugar, AsA, and GSH contents were considerably increased with CB. Accumulated content of organic solutes, especially soluble sugars (the main solutes) are involved in cell osmotic adjustment in glycophytic plants exposed to osmotic and salt stress [20]. Results herein showed that soybean plants with CB or CB + GSH led to a considerable increase in soluble sugars compared with control plants without CB or GSH. GSH participated in

accumulation of soluble sugars that could be attributed to the protective role of GSH in photosynthetic systems and in salt tolerance by maintaining the redox status [20, 56]. Moreover, accumulation of protein under salt stress could provide a storage N form, which is reused under excessive stress and may also play a positive role in osmotic adjustments [57]. Treatment with CB or CB + GSH considerably increased protein content of soybean plants. CB cultures are capable of improving plant growth and increasing extracellular proteins (in the range of 32–82 $\mu\text{g ml}^{-1}$) and amino acids array [58].

Salt stress causes oxidative damages in plant tissues by stimulating ROS overproduction. The $\text{O}_2^{\cdot-}$ produced due to stress in plant tissues is transformed by the enzyme SOD to H_2O_2 (a powerful oxidant) [59], which is prevented by ascorbate-glutathione cycle. This due to that SOD activity increases linearly with prolonged stress conditions, which in turn is attributed to that SOD is responsible for declining the oxidative stress-derived ROS. The enzyme CAT plays a crucial role in eliminating the oxidative stress-derived ROS like H_2O_2 by converting it to O_2 and H_2O [60]. In this study, using CB or CB + GSH resulted in an increase of CAT activity under a salty medium. It has been reported in [20] that CB or CB + GSH increased the levels of antioxidant substances and improved the activities of the antioxidant enzymes; SOD, CAT, and GPOX in common bean plants under salt stress. It has been indicated in [61] that there are a number of mechanisms developed by CB that defend against stress, including production of photo-protective compounds like mycosporine-like amino acids (MAAs) and scytonemin, enzymes like SOD, CAT and GPOX, repairing of DNA damage, and synthesizing shock proteins.

Salt stress causes disruption in ionic equilibrium like Na^+ influx that causes dissipation of membrane potential and facilitates Cl^- uptake down the chemical gradient. Na^+ ion is toxic to cell metabolism and has a dangerous influence on some enzymes functioning. High Na^+ ion level causes osmotic imbalance, disorganization of membranes, and inhibition of cell division and expansion. Further, high Na^+ ion level leads to a reduction in photosynthesis and ROS production [20, 45]. With CB, it has been reported in [62] that accumulating the internal osmotica in inorganic ions form and preventing the intracellular Na^+ ion accumulation by reducing Na^+ influx, and by effective efflux mechanisms or metabolic adjustments have been in depth explained. Na^+ extrusion in CB is driven by the Na^+/H^+ antiporter that is energized by improved activity of cytochrome oxidase. Inhibiting the Na^+ influx appears a major mechanism for CB survival against salt stress, and synthesis of salt-stress proteins is found out to occur in CB. As a result, CB cause an inhibition in the toxic Na^+ ion accumulation and ensure ionic equilibrium with increased contents of N, P, and K^+ [20], which are agreed with our results (Table 7). Therefore, there was a significant recovery in soybean growth at salt stress conditions. It has been reported in [14] that maintaining the ionic balance under salt stress is a prerequisite to protect plant against toxic ion build-up, with K^+ accumulation and Na^+ at a minimum content in soybean leaves. The impact of N on plant growth and its development connects, often, with photosynthesis process [63]. Therefore, in this study, increased N accumulation with CB treatment improved growth and yield attributes. In [64], it has been reported that CB have the capability of fixing the atmospheric Na and possess some soil phosphate, solubilizing the insoluble phosphate by excreting organic acids, which solve the common problem of P chemical fixation in all soil types. These beneficial effects (indirect advantages for plants) of CB are supported by the other beneficial effects (direct advantages for plants) of GSH that deals effectively with ROS to increased plant tolerance to salt stress.

Conclusions

Pretreatment with CB bio-fertilizer to the environment possessed high salt stress appeared to be helpful to performance (growth, development, and yield) and the physio-biochemical processes of soybean plant. The integrative CB (for seed inoculation) + GSH (for plant foliar spray) treatment was most effective compared to using individual CB or GSH. This effective integrative treatment had improved levels of physio-biochemical attributes and antioxidant (non-enzymatic and enzymatic) defence systems and raised salt stress tolerance in soybean plants. Therefore, the integrative CB + GSH treatment has been concluded to be a helpful strategy for improving growth and increasing yield of soybean plants when grown under salt-affected soils.

Conflict of Interest

The authors declare that there is no conflict of interest.
